## Introduction

The Ornstein–Uhlenbeck (OU) process is a classical mean-reverting stochastic process used in a variety of applications including physics, finance, and queueing theory. In this document, we simulate and analyze both the standard OU process and its **reflected** form (ROU) in one and two dimensions, examining key properties such as stationarity, ergodicity, and convergence.

## 1. Ornstein–Uhlenbeck Process (1D)

The 1D OU process is governed by the stochastic differential equation:

$$dX_t = -\theta(X_t - \mu) dt + \sigma dW_t \tag{1}$$

Where: -  $X_t$ : state at time  $t$  -  $\mu$ : long-run mean -  $\theta > 0$ : mean reversion speed -  $\sigma$ : volatility -  $dW_t$ : standard Brownian motion increment

This process is stationary and has a well-defined limiting distribution:

$$\text{Var}(X_t) = \frac{\sigma^2}{2\theta} \tag{2}$$

(see Lemma 7, Huang & Pang, 2022)

## Ornstein–Uhlenbeck Process (1D)

$\{\text{=latex}\} \ \text{\vspace{10pt}}$

## 2. Stationarity and Ergodicity

The OU process is **second-order stationary**: its mean and variance are time-invariant, and autocovariance depends only on lag. It is also **ergodic**, meaning:

$$\lim_{T \rightarrow \infty} \frac{1}{T} \int_0^T X_t dt = \mathbb{E}[X_t] = \mu \quad (3)$$

(see Theorem 2.4, Huang & Pang, 2022)  $\{\text{=latex}\} \ \text{\vspace{10pt}}$  —

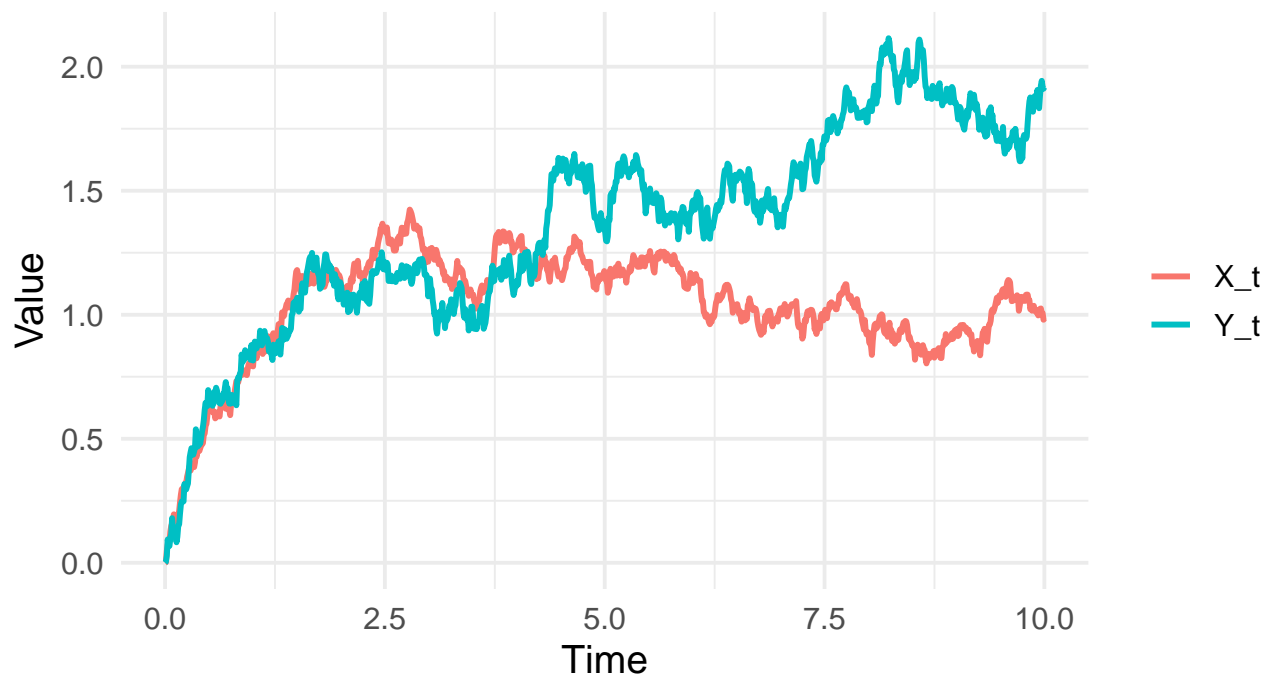

## 3. Multivariate OU Process (2D)

We now extend the OU process to two dimensions, where the state vector  $\mathbf{X}_t = (X_t, Y_t) \in \mathbb{R}^2$  evolves as:

$$d\mathbf{X}_t = -\Theta(\mathbf{X}_t - \boldsymbol{\mu}) dt + \Sigma d\mathbf{W}_t \quad (4)$$

Where: -  $\Theta$ : mean reversion matrix -  $\Sigma$ : diffusion matrix -  $\boldsymbol{\mu}$ : long-run mean vector -  $d\mathbf{W}_t$ : vector of independent Brownian motions

### 4. Reflected Ornstein–Uhlenbeck Process (1D)

We now simulate a **reflected OU process** in 1D, where the process is constrained to remain in  $\mathbb{R}_+$ . This imposes a Skorokhod reflection at the boundary  $X_t = 0$ , approximated here by taking the absolute value of a standard OU trajectory.

## True Reflection of Ornstein–Uhlenbeck Process at $x = 0$

`{=latex} \vspace{10pt}`

## 5. Local Time Approximation

Following Huang & Pang (2022), the reflected process introduces a local time  $L_t$ , which increases only when  $X_t = 0$ . To approximate this numerically, we accumulate the negative excursions of the unreflected path:

### Accumulated Local Time Process $L(t)$

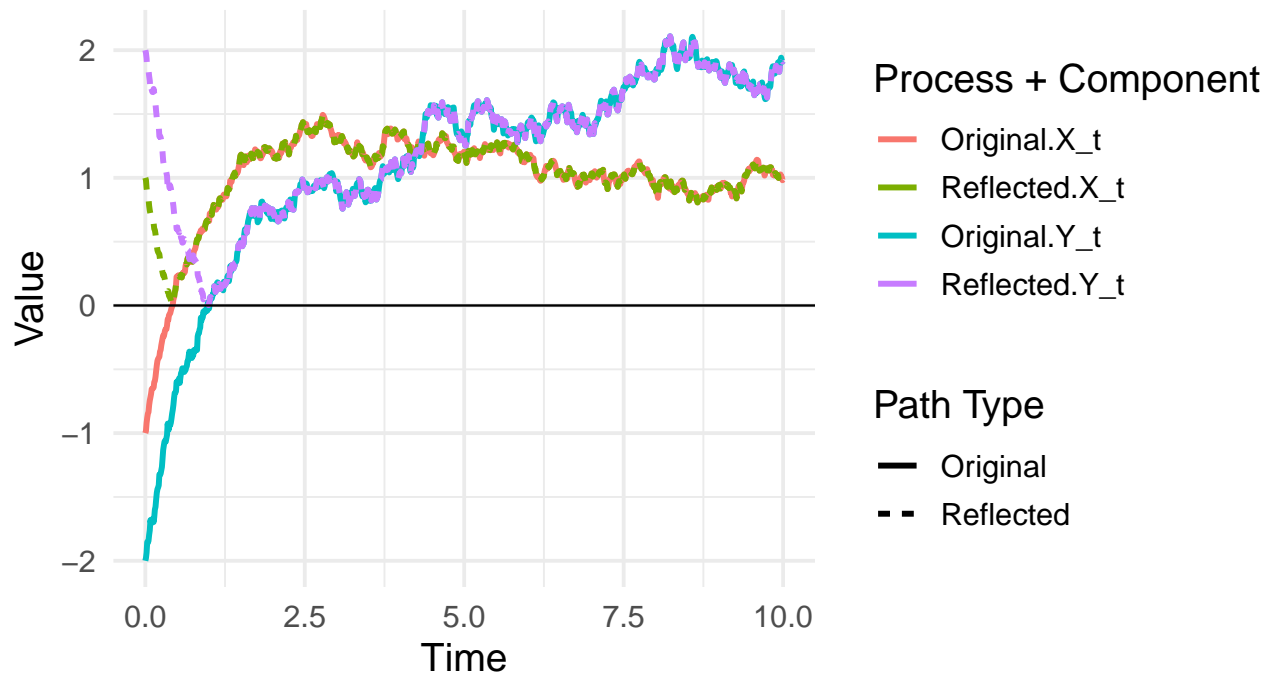

`{=latex} \vspace{10pt}`

## 6. Reflected OU Process in $\mathbb{R}_+^2$

We extend the OU system to 2D and impose reflection into the nonnegative orthant by projecting any negative value to zero.

## Original vs Reflected 2D OU Process ( $|X_t|$ and $|Y_t|$ )

$\{\text{=latex}\} \text{ \vspace{10pt}}$

### 7. Autocorrelation Function (ACF)

#### Autocorrelation of OU Process

OU processes exhibit exponentially decaying autocorrelations:  $\rho(\tau) = e^{-\theta\tau}$ .

---

## 8. Stationary Distribution Convergence

We compare empirical distribution at time  $T$  to the theoretical stationary normal:

### Empirical Stationary Distribution vs Theoretical Norm

Huang & Pang (2022) confirm the convergence of the ROU process toward a stationary distribution under bounded local time and ergodicity (Theorem 2.4).
